AB HrpN, the **hypersensitive response elicitor**
from **Erwinia** amylovora, stimulated K+ outward rectifying
currents in Arabidopsis thaliana suspension cells. It also decreased anion
currents. These data demonstrate the ability of harpin to regulate
different plasma membrane ion channels, putative components of signal
transduction chains leading to defense responses and programmed cell
death.

AB The invention provides sequences encoding active fragments of a **hypersensitive response** elicitor protein which does not elicit a **hypersensitive response** in plants. Specifically, the fragments are derived from **hypersensitive response** elicitor proteins from Erwinia amylovora (gene hrpN) and/or Pseudomonas syringae (gene hrpZ). Isolated fragments of **hypersensitive response** elicitor proteins have the following activities: imparting disease resistance to plants, enhancing plant growth, and/or controlling insects on plants. This can be achieved by applying the fragments of a **hypersensitive response** elicitor in a non-infectious form to plants or plant seeds, or by using transgenic plants or plant seeds transformed with a DNA mol. encoding the **hypersensitive response** elicitor fragment.

AB The invention describes a new method to isolate disease resistance genes in plants. The method comprises transient expression in susceptible plants (e.g., Nicotiana benthamiana) of large nos. of R-gene homologs or non-host inducible genes isolated from non-host resistant plants. These plants can be screened for either disease resistance or ability to respond with a **hypersensitive response** to pathogen-elicitor subjection. The invention also reports several R-genes and non-host inducible genes that have been successfully isolated from tobacco using the described method. These R-genes trigger a **hypersensitive response** in tobacco that is dependent on the presence of the ubiquitous **Phytophthora** infestans elicitor INF1 (the pathogen responsible for late blight disease in potato). Class I R-genes encode proteins with a nucleotide-binding site and a conserved stretch of amino acids with the consensus sequence GLPLAL, and class II R-genes encode proteins with a conserved putative membrane anchor. The presented R-genes are predicted to be both the first R-genes isolated that confer resistance against P. infestans and the first R -genes involved in non-host resistance. A protein factor designated Nhr1 that interacts with the P. infestans elicitor INF1 was also cloned and sequenced, as well as a protein designated TOB-F2 that controls wild fire disease caused by the Pseudomonas tabaci pathogen.

AB Desiccation of cuttings removed from ornamental plants is inhibited by treating the cutting with a **hypersensitive response** elicitor protein or polypeptide derived from plant pathogen. The ornamental plants can be transgenic plants which express a heterologous

hypersensitive response elicitor protein or polypeptide or the ornamental plants can be treated via topical application with a **hypersensitive response** elicitor protein or polypeptide. Alternatively, cuttings from the ornamental plant can be treated with a **hypersensitive response** elicitor protein or polypeptide, independent of any treatment provided to the ornamental plant from which the cutting is removed.

AB Resistance to **Phytophthora** infestans was studied in potato and wild Solanum species, with an emphasis on molecular and cellular biology of the plant-pathogen interaction. A cytological survey was carried out on the resistance responses of Solanum plants to various isolates of P. infestans. The **hypersensitive response** was always associated with resistance and the severity of this response varied between different plants. Variation in the growth rates of **hypersensitive response** lesions between plants suggested that defence mechanisms other than the **hypersensitive response** operated at different levels. Pathogenesis-related gene expression levels were used as molecular markers to measure systemic acquired resistance levels. The plant components of the molecular interaction in the **hypersensitive response** were further studied, with emphasis on the R genes and the Pto kinases. Analysis of the amino acid sequence characteristics revealed that the Pto-like sequences are highly conserved.

AB The present invention relates to methods of improving the effectiveness of transgenic plants, either by maximizing the benefit of transgenic trait in transgenic plants or overcoming deleterious effects on growth, stress tolerance, disease resistance, or insect resistance in transgenic plants expressing a transgenic trait. By applying a **hypersensitive response** elicitor protein or polypeptide to a transgenic plant expressing a transgene which confers a transgenic trait, or by prepg. a transgenic plant expressing both a transgene which confers a transgenic trait and a second transgene which confers **hypersensitive response** elicitor expression, it is possible to realize the max. benefit of the transgenic trait or overcome deleterious effects on growth, stress tolerance, disease or insect resistance, male sterility, modified flower color or biochem. modified plant products which result from or accompany expression of the transgene conferring the transgenic trait.

The **hypersensitive response** elicitor protein can be applied to the plant or seed at a concn. greater than 0.5 nM by spraying, injection, dusting, immersion or leaf abrasion in water, aq. solns., slurries or powder.

AB The present invention is directed to an isolated protein which serves as a receptor in plants for a plant pathogen **hypersensitive response** elicitor. Also disclosed are nucleic acid mols. encoding such receptors as well as expression vectors, host cells, transgenic plants, and transgenic plant seeds contg. such nucleic acid mols. Both the protein and nucleic acid can be used to identify agents targeting plant cells to enhance a plant's receptivity to treatment with a **hypersensitive response** elicitor and to directly impart plant growth enhancement as well as resistance against disease, insects, and stress. Thus, the Arabidopsis thaliana cDNA and gene for Erwinia amylovora harpin-binding protein HrBP1 were cloned and sequenced. A partial cDNA for the rice HrBP1 homolog was also cloned and sequenced. HrBP1 was found everywhere is the A. thaliana plant. HrBP1 mRNA was found in many different plants (monocots as well as dicots). Silencing of HrBP1 expression in A. thaliana enhanced its resistance to Pseudomonas syringae p.v. tomato infection. Overexpression of HrBP1 in tobacco resulted in enhanced resistance to tobacco mosaic virus.

AB **Phytophthora** infestans, the agent of potato and tomato late blight disease, produces a 10-kD extracellular protein, INF1 elicitin. INF1 induces a **hypersensitive response** in a restricted number of plants, particularly those of the genus Nicotiana. In virulence assays with different P. infestans isolates, five Nicotiana species displayed resistance responses. In all of the interactions, after inoculation with P. infestans zoospores, penetration of an epidermal cell was observed, followed by localized necrosis typical of a **hypersensitive response**. To determine whether INF1 functions as an avirulence factor in these interactions, we adopted a gene-silencing strategy to inhibit INF1 production. Several transformants deficient in inf1 mRNA and INF1 protein were obtained. These strains remained pathogenic on host plants. However, in contrast to the wild-type and control transformant strains, INF1-deficient strains induced disease lesions when inoculated on N. benthamiana. These results demonstrate that the elicitin INF1 functions as an avirulence factor in the interaction between N. benthamiana and P. infestans.

AB The cry-b sequence encoding a basic elicitin (cryptogein B) from **Phytophthora** cryptogea, was co-transformed into **Phytophthora** infestans. The copy number of the cry-b sequence varied in co-transformants. Nevertheless, in all cases the alien elicitin gene was transcribed, translated and the protein secreted in vitro from such transformants. Moreover, the secreted cryptogein B from P. infestans co-transformants increased their ability to cause a **hypersensitive response**-like necrosis of tobacco leaves. It was thus concluded that the transfer of a single gene encoding a basic elicitin from one **Phytophthora** species to another can dramatically alter the phenotypic interaction of the transformed species with tobacco.

AB The present invention relates to a method of imparting pathogen resistance to plants. This involves applying a **hypersensitive response** elicitor polypeptide or protein in a non-infectious form to a plant seed under conditions where the polypeptide or protein contacts cells of the plant seed. The present invention is also directed to a pathogen resistance imparting plant seed. Alternatively, transgenic plant seeds contg. a DNA mol. encoding a **hypersensitive response** elicitor polypeptide or protein can be planted in soil and a plant can be propagated from the planted seed under conditions effective to impart pathogen resistance to the plant. Elicitor proteins and their gene sequences are provided from Erwinia chrysanthemi, E. amylovora, Pseudomonas syringae, P. solanacearum, Xanthomonas campestris cv. glycines, and X. campestris cv. pelargonii.

AB The present invention relates to a method of controlling insects on plants. This involves applying a **hypersensitive response** elicitor polypeptide or protein in a non-infectious form to a plant or plant seed under conditions effective to control insects on the plant or plants produced from the plant seed. Alternatively, transgenic plants or transgenic plant seeds transformed with a DNA mol. encoding a **hypersensitive response** elicitor polypeptide or protein can be provided and the transgenic plants or plants resulting from the transgenic plant seeds are grown under conditions effective to control insects. Thus, tobacco seedlings generated from harpin-soaked seeds (an elicitor from Erwinia amylovora) are far more resistant to aphid infection than control plants. Similarly, cotton aphids (Aphis gossypii) are controlled by foliar application of HP-1000 (a hypersensitive elicitor from Erwinia amylovora) on cotton plants.

AB The rapid and effective activation of disease resistance responses is essential for plant defense against pathogen attack. These responses are initiated when pathogen-derived molecules (elicitors) are recognized by the host. We have developed a strategy for creating novel disease resistance traits whereby transgenic plants respond to infection by a virulent pathogen with the production of an elicitor. To this end, we generated transgenic tobacco plants harboring a fusion between the pathogen-inducible tobacco hsr203J gene promoter and a **Phytophthora** cryptogea gene encoding the highly active elicitor cryptogein. Under noninduced conditions, the transgene was silent, and no cryptogein could be detected in the transgenic plants. In contrast, infection by the virulent fungus P. parasitica var nicotianae stimulated cryptogein production that coincided with the fast induction of several defense genes at and around the infection sites. Induced elicitor production resulted in a localized necrosis that resembled a P. cryptogea-induced **hypersensitive response** and that restricted further growth of the pathogen. The transgenic plants displayed enhanced resistance to fungal pathogens that were unrelated to

Phytophthora species, such as Thielaviopsis basicola, Erysiphe cichoracearum, and Botrytis cinerea. Thus, broad-spectrum disease resistance of a plant can be generated without the constitutive synthesis of a transgene product.

AB A method of imparting pathogen resistance to plants is decribed. This involves applying a **hypersensitive response** elicitor polypeptide or protein in a non-infectious form to a plant under conditions where the polypeptide or protein contacts cells of the plant. The invention is also directed to a pathogen resistant plant and a compn. for imparting pathogen resistance to plants. Thus, treatment of tomato plants with harpin or Escherichia coli DH5 (pCPP430), which produces harpin, results in induced resistance in the plants to southern bacterial wilt caused by Pseudomonas solanacearum K60.

AB Most species of the genus **Phytophthora** produce 10-kDa extracellular protein elicitors, collectively termed elicitins. Elicitins induce **hypersensitive response** in a restricted number of plants, particularly in the genus Nicotiana within the Solanaceae family. A cDNA encoding INF1, the major secreted elicitin of **Phytophthora** infestans, a pathogen of solanaceous plants, was isolated and characterized. The expression of the corresponding inf1 gene during the disease cycle of P. infestans was analyzed. inf1 was shown to be expressed in mycelium grown in various culture media, whereas it was not expressed in sporangiospores, zoospores, cysts, and germinating cysts. In planta, during infection of potato, particularly during the biotrophic stage, expression of inf1 was down-regulated compared to in vitro. The highest levels of expression of inf1 were observed in in vitro grown mycelium and in late stages of infection when profuse sporulation and leaf necrosis occur. The potential role of INF1 as an elicitor in interactions between P. infestans and Solanum species was investigated. Nineteen lines, representing nine solanaceous species with various levels of resistance to P. infestans, were tested for response to an Escherichia coli expressed INF1. Within the genus Solanum, resistance to P. infestans did not appear to be mediated by a defense response elicited by INF1. However, INF1 recognition could be a component of nonhost resistance of tobacco to P. infestans.

AB Desiccation of cuttings removed from ornamental plants is inhibited by treating the cutting with a **hypersensitive response elicitor** protein or polypeptide derived from plant pathogen. The ornamental plants can be transgenic plants which express a heterologous **hypersensitive response elicitor** protein or polypeptide or the ornamental plants can be treated via topical application with a **hypersensitive response elicitor** protein or polypeptide. Alternatively, cuttings from the ornamental plant can be treated with a **hypersensitive response elicitor** protein or polypeptide, independent of any treatment provided to the ornamental plant from which the cutting is removed.

AB The present invention relates to methods of improving the effectiveness of transgenic plants, either by maximizing the benefit of transgenic trait in transgenic plants or overcoming deleterious effects on growth, stress tolerance, disease resistance, or insect resistance in transgenic plants expressing a transgenic trait. By applying a **hypersensitive response elicitor** protein or polypeptide to a transgenic plant expressing a transgene which confers a transgenic trait, or by prepg. a transgenic plant expressing both a transgene which confers a transgenic trait and a second transgene which confers **hypersensitive response elicitor** expression, it is possible to realize the max. benefit of the transgenic trait or overcome deleterious effects on growth, stress tolerance, disease or insect resistance, male sterility, modified flower color or biochem. modified plant products which result from or accompany expression of the transgene conferring the transgenic trait. The **hypersensitive response elicitor** protein can be applied to the plant or seed at a concn. greater than 0.5 nM by spraying, injection, dusting, immersion or leaf abrasion in water, aq. solns., slurries or powder.

AB The present invention is directed to an isolated protein which serves as a receptor in plants for a plant pathogen **hypersensitive response elicitor**. Also disclosed are nucleic acid mols. encoding such receptors as well as expression vectors, host cells, transgenic plants, and transgenic plant seeds contg. such nucleic acid mols. Both the protein and nucleic acid can be used to identify agents targeting plant cells to enhance a plant's receptivity to treatment with a **hypersensitive response elicitor** and to directly impart plant growth enhancement as well as resistance against disease, insects, and stress. Thus, the Arabidopsis thaliana cDNA and

gene for Erwinia amylovora harpin-binding protein HrBP1 were cloned and sequenced. A partial cDNA for the rice HrBP1 homolog was also cloned and sequenced. HrBP1 was found everywhere is the A. thaliana plant. HrBP1 mRNA was found in many different plants (monocots as well as dicots). Silencing of HrBP1 expression in A. thaliana enhanced its resistance to Pseudomonas syringae p.v. tomato infection. Overexpression of HrBP1 in tobacco resulted in enhanced resistance to tobacco mosaic virus.

AB The present invention relates to a chimeric gene that includes a first DNA mol. encoding a **hypersensitive response elicitor** protein or polypeptide, a promoter operably linked 5' to the first DNA mol. to induce transcription of the first DNA mol. in response to activation of the promoter by an **oomycete**, and a 3' regulatory region operably linked to the first DNA mol. Also disclosed are an expression system and a host cell contg. the chimeric gene. The present invention also relates to a transgenic plant resistant to disease resulting from **oomycete** infection, the transgenic plant including the chimeric gene, wherein the promoter induces transcription of the first DNA mol. in response to infection of the plant by an **oomycete**. Transgenic seeds and transgenic cultivars obtained from the transgenic plant are also disclosed. Addnl. aspects of the present invention include methods of making a recombinant plant cell and a transgenic plant.

AB The dynamics of microtubular cytoskeleton were studied in tobacco (Nicotiana tabacum cv Xanthi) cells in response to two different plant defense elicitors: cryptogein, a protein secreted by **Phytophthora** cryptogea and oligogalacturonides (OGs), derived from the plant cell wall. In tobacco plants cryptogein triggers a hypersensitive-like response and induces systemic resistance against a broad spectrum of pathogens, whereas OGs induce defense responses, but fail to trigger cell death. The comparison of the microtubule (MT) dynamics in response to cryptogein and OGs in tobacco cells indicates that MTs appear unaffected in OG-treated cells, whereas cryptogein treatment caused a rapid and severe disruption of microtubular network. When hyperstabilized by the MT depolymerization

inhibitor, taxol, the MT network was still disrupted by cryptogein treatment. On the other hand, the MT-depolymerizing agent oryzalin and cryptogein had different and complementary effects. In addition to MT destabilization, cryptogein induced the death of tobacco cells, whereas OG-treated cells did not die. We demonstrated that MT destabilization and cell death induced by cryptogein depend on calcium influx and that MT destabilization occurs independently of active oxygen species production. The molecular basis of cryptogein-induced MT disruption and its potential significance with respect to cell death are discussed.

AB The invention provides sequences encoding active fragments of a **hypersensitive response elicitor** protein which does not elicit a hypersensitive response in plants. Specifically, the fragments are derived from **hypersensitive response elicitor** proteins from Erwinia amylovora (gene hrpN) and/or Pseudomonas syringae (gene hrpZ). Isolated fragments of **hypersensitive response elicitor** proteins have the following activities: imparting disease resistance to plants, enhancing plant growth, and/or controlling insects on plants. This can be achieved by applying the fragments of a **hypersensitive response elicitor** in a non-infectious form to plants or plant seeds, or by using transgenic plants or plant seeds transformed with a DNA mol. encoding the **hypersensitive response elicitor** fragment.

AB The present invention relates to a method of controlling insects on plants. This involves applying a **hypersensitive response elicitor** polypeptide or protein in a non-infectious form to a plant or plant seed under conditions effective to control insects on the plant or plants produced from the plant seed. Alternatively, transgenic plants or transgenic plant seeds transformed with a DNA mol. encoding a **hypersensitive response elicitor** polypeptide or protein can be provided and the transgenic plants or plants resulting from the transgenic plant seeds are grown under conditions effective to control insects. Thus, tobacco seedlings generated from harpin-soaked seeds (an elicitor from Erwinia amylovora) are far more resistant to aphid infection than control plants. Similarly, cotton aphids (Aphis gossypii) are controlled by foliar application of HP-1000 (a hypersensitive elicitor from Erwinia amylovora) on cotton plants.

AB A method of stimulating plant growth using **hypersensitive response elicitor** polypeptides is described. The pathogen-free polypeptide can be applied to the plants, or to seed, or the plants may transformed with a gene for the elicitor. The elicitor can be used to accelerate germination and early growth when applied to seed or to advance maturation and ripening when applied to older plants. Tomato seed incubated in an aq. soln. (1.25-20 .mu.g/mL) of harpin for 24 h at 28.degree. before sowing showed more rapid and extensive germination than control plants (38-43% germination on day 5 vs. 27% for control plants and 51-59% germination on day 9 vs. 40% for controls). Seedling growth was also faster. Field trials showed that harpin was also effective in stimulating the growth of seedlings. Ripening of raspberries was also stimulated by application of harpin.

AB A 32 kDa glycoprotein whose effects in tobacco and other Nicotiana mimic a typical hypersensitive response, was isolated from **Phytophthora** megasperma. Infiltration of a few nanograms of the protein into leaves caused the formation of lesions that closely resemble hypersensitive response lesions. Transcripts of genes encoding enzymes of the phenylpropanoid and sesquiterpenoid pathways accumulated rapidly after elicitor application followed by salicylic acid prodn. Cellular damage, restricted to the infiltrated zone, occurred only several hours later, at a time when expression of PR protein genes was activated. After several days, systemic acquired resistance was also induced. Thus, tobacco plant cells that perceived the glycoprotein generated a cascade of signals

acting at local, short, and long distances, and causing the coordinate expression of specific defense responses in a way similar to hypersensitivity to tobacco mosaic virus. The glycoprotein represents a powerful tool to investigate further the signals and their transduction pathways involved in induced disease resistance. It may also be useful to engineer broad disease protection in a Nicotianae and possibly into crop plant species.

AB M.26 apple rootstock was transformed with different hrpN gene constructs to evaluate their potential for increasing resistance to fire blight. One approach was to attempt to induce a resistance reaction in transgenic apple by low-level expression of harpin from the nos **promoter**. A second approach was to engineer programmed cell death by high-level expression of harpin from a pathogen-inducible **promoter**. Since the cell wall is thought to be the site of harpin and host-cell interaction, constructs for both approaches were made with and without a signal peptide sequence (SS) to direct harpin to the intercellular space. For the first approach, two plasmid binary vectors contg. hrpN gene constructs, pBINPLUS/ Pnos-hrpN-Tnos and pBINPLUS/ Pnos-antihrpN-Tnos (antisense version), were transferred to M.26 explants using Agrobacterium tumefaciens. Regenerants were obtained on media contg. kanamycin (100 mg/l) and transformation was confirmed by NPTII ELISA and PCR anal. for the presence of the hrpN gene. Expression of harpin was demonstrated by western anal. For the second approach, the pathogenesis-related protein gene **promoter** (**gst**-1, formerly prpl-1) of **potato** is being evaluated in apple for its ability to be specifically induced by apple pathogens, including Erwinia amylovora.

AB The .lambda.WIR526 clone was isolated from a wheat (Triticum aestivum L. cv Cheyenne) genomic .lambda.EMBL3 library using the **pathogen-induced** cDNA clone WIR5 as a probe. The complete nucleotide sequence of a 3.2-kb HindIII/BamHI DNA fragment of this clone hybridizing with WIR5 cDNA clone was detd. on both strands. Anal. of the 3196-bp sequence revealed that it contains a gene very similar to the putative wheat glutathione-S-transferase gene gstA1. Diagrams of this gene, which was named gstA2, and gstA1 are given. Whereas the first 1565 bp of the sequenced fragment are unrelated to gstA1, the sequence downstream exhibits an av. similarity of 90% to the gstA1 gene. Most of the discrepancies are accounted for by small deletions and insertions in the non-coding regions. However, compared to gstA1, there is a 1-bp deletion after position 2907 in gstA2, which corresponds to the second to last codon in the third exon of gstA1. This shifts the reading frame and results in an extension of the putative encoded protein to 291 amino acids, 62 amino acids longer than the gstA1-encoded one. Apart from this extension, the protein sequences are 95% identical. Since the known GST subunit sizes appear to be conserved in evolution and are all between 209 and 229 amino acids it is possible that this frame-shift mutation would render the gstA2 gene product non-functional.

AB Pathogenesis-related (PR) proteins form a heterogeneous group of host-encoded, low-mol.-mass proteins that are secreted through the exocytic pathway. They are synthesized by the plant in response to various stimuli, including pathogen attack or exposure to certain chems. The PRB-1b gene of Nicotiana tabacum codes for a basic-type PR-1 protein whose transcription is regulated by ethylene. A minimal ethylene-responsive **promoter** element was defined by deletion anal. in transgenic tobacco plants. **Promoter** sequences contg. 213 bp or more were sufficient to enhance a 20-fold increase of .beta.-glucuronidase reporter gene expression in transgenic tobacco leaves exposed to 20 .mu.L L-1 of ethylene, while 67 bp were not sufficient to trigger ethylene responsiveness. All the constructs that retained ethylene inducibility exhibited phloem-specific activity, which was constitutive in petiole and pedicel abscission zones. This functional study was correlated to an in vitro screening of the major nuclear proteins' binding sites present on the **promoter**. Gel-shift anal. using nuclear exts. from ethylene-treated and non-treated plants revealed five sequence-specific protein-DNA complexes on **promoter** sequences spanning -863 to -142 bp. Constitutive expression of the basic-type PR-1 genes at the leaf and petiole or flower and pedicel interfaces may represent pre-emption of plant defenses against potential pathogens, suggesting a functional similarity to **pathogen-induced** expression in the leaf.

AB A flax gene (Fis1) that is induced by infection of the plant with the rust pathogen Melampsora lini is characterized and the SRR (susceptible reaction-responsive) **promoter** region identified for use in driving the expression of reporter genes or genes conferring resistance to phytopathogenic fungi is described. The gene can be used to identify similar genes under control of SRR promoters in other plants and a gene (Mis1) that is induced by Puccinia sorghi infection of corn is identified. The Fis1 gene was cloned by obtaining a cDNA clone for a **pathogen-induced** transcript and using it to screen for the corresponding gene. The **promoter** was used to drive .beta.-glucuronidase gene in flax.

AB The rapid and effective activation of disease resistance responses is essential for plant defense against pathogen attack. These responses are initiated when pathogen-derived molecules (elicitors) are recognized by the host. We have developed a strategy for creating novel disease resistance traits whereby transgenic plants respond to infection by a virulent pathogen with the production of an elicitor. To this end, we generated transgenic tobacco plants harboring a fusion between the pathogen-inducible tobacco hsr203J gene **promoter** and a Phytophthora cryptogea gene encoding the highly active elicitor cryptogein. Under noninduced conditions, the transgene was silent, and no cryptogein could be detected in the transgenic plants. In contrast, infection by the virulent fungus P. parasitica var nicotianae stimulated cryptogein production that coincided with the fast induction of several defense genes at and around the infection sites. Induced elicitor production resulted in a localized necrosis that resembled a P. cryptogea-induced hypersensitive response and that restricted further growth of the pathogen. The transgenic plants displayed enhanced resistance to fungal pathogens that were unrelated to Phytophthora species, such as Thielaviopsis basicola, Erysiphe cichoracearum, and Botrytis cinerea. Thus, broad-spectrum disease resistance of a plant can be generated without the constitutive synthesis of a transgene product.

AB A method for protection of plants against pathogen,s comprising **pathogen-induced** interaction of a plant-resistance gene

(R) product and a pathogen-avirulence (A) gene product, both genes being expressed in the plant, is described. Thus, an A gene is introduced into an R gene-contg. plant. Both genes are regulated such that they are simultaneously expressed at the site of pathogen infection, and the expression is induced by a broad range of pathogens. Alternatively, both R and A genes are introduced into the plant and their expression is regulated as described. The cDNA for the A gene avr9 of Cladosporium fulvum was cloned and sequenced. This cDNA encodes a 63-amino acid precursor of the 28-amino acid **elicitor**. This **elicitor** induces resistance in tomato cultivars which have the R gene Cf9. A virulent C. fulvum expressing the avr9 gene was converted to avirulence on tomatoes with Cf9 genotype.

AB The rapid and effective activation of disease **resistance** responses is essential for **plant** defense against pathogen attack. These responses are initiated when pathogen-derived mols. (elicitors) are recognized by the host. A strategy was developed for creating novel disease **resistance** traits whereby transgenic plants respond to infection by a virulent pathogen with the prodn. of an elicitor. Thus, transgenic tobacco plants harboring a fusion between the pathogen-inducible tobacco hsr203J gene promoter and a **Phytophthora** cryptogea gene encoding the highly active elicitor cryptogein were generated. Under noninduced conditions, the transgene was silent, and no cryptogein could be detected in the transgenic plants. In contrast, infection by the virulent fungus P. parasitica var nicotianae stimulated cryptogein prodn. that coincided with the fast induction of several defense genes at and around the infection sites. Induced elicitor prodn. resulted in a localized necrosis that resembled a P. cryptogea-induced hypersensitive response and that restricted further growth of the pathogen. The transgenic plants displayed enhanced **resistance** to fungal pathogens that were unrelated to **Phytophthora** species, such as Thielaviopsis basicola, Erysiphe cichoracearum, and Botrytis cinerea. Thus, broad-spectrum disease **resistance** of a **plant** can be generated without the constitutive synthesis of a transgene product.

AB The present invention provides pathogen-**resistant** transgenic plants and methods of making the plants. The transgenic plants display enhanced **resistance** to a variety of fungal, bacterial and viral **plant** pathogens due to expression of a gene that increases the unsatd. fatty acid content of the **plant**'s cells, as compared with an equiv., but non-**transformed plant**. The preferred embodiment of the invention is a **plant** expressing a heterologous .DELTA.-9 desaturase gene from yeast, which particularly increases cytosolic quantities of 16:1, 16:2 and 18:1 fatty acids.

AB The hrmA gene from Pseudomonas syringae pv. syringae has previously been shown to confer avirulence on the virulent bacterium Pseudomonas syringae pv. tabaci in all examined tobacco cultivars. We expressed this gene in tobacco (Nicotiana tabacum cv. KY14) plants under the control of the tobacco DELTA 0.3 TobRB7 promoter, which is induced upon nematode infection in tobacco roots. A basal level of hrmA expression in leaves of transgenic plants activated the expression of pathogenesis-related genes, and the transgenic plants exhibited high levels of **resistance** to multiple pathogens: tobacco vein mottling virus, tobacco etch virus, black shank fungus **Phytophthora** parasitica [**Phytophthora** nicotianae var. parasitica] isolate 62, and wild fire bacterium Pseudomonas syringae pv. tabaci. However, the hrmA transgenic plants were not significantly more **resistant** to root-knot nematodes (Meloidogyne javanica and M. hapla). Our results suggest a potential use of controlled low-level expression of bacterial avr genes, such as hrmA, in plants to generate broad-spectrum **resistance** to bacterial, fungal and viral pathogens.

AB To engineer crop disease **resistance** by utilizing natural defense mechanism that was expressed in the incompatible host-pathogen interactions is expected to result in a durable and broad-spectrum **resistance**. In order to prove this viewpoint, we amplified the coding region of the glucose oxidase (GO) gene from Aspergillus niger via PCR and fused it to the pathogen-inducible promoter, Prpl-1. The chimeric gene was cloned into a **plant** expression vector and conjugated into Agrobacterium. Twenty-three transgenic potato plants were obtained by Agrobacterium-mediated **transformation**. The integration of GO gene was confirmed by Southern hybridization and the GO gene expression was identified with KI-starch color reaction. **Phytophthora** infestans inoculation revealed that the expression of the chimeric transgene was induced by pathogen infection. Most of the transgenic plants exhibited various degrees of enhanced disease **resistance**. Four of them had lesion sizes reduced to less than half of the non-transgenic controls. One **plant** showed disease **resistance** of the hypersensitive response. These results testified the feasibility of our strategy of expressing GO transgene under the control of the disease-inducible promoter in engineering crop disease **resistance**.

AB Here we describe a strategy for engineering transgenic plants with broad-spectrum **resistance** to bacterial and fungal phytopathogens. We expressed a synthetic gene encoding a N terminus-modified, cecropin-melittin cationic peptide chimaera (MsrA1), with broad-spectrum antimicrobial activity. The synthetic gene was introduced into two potato (Solanum tuberosum) cultivars, Desiree and Russet Burbank, and stable incorporation was confirmed by PCR and DNA sequencing, and expression confirmed by reverse transcription (RT)-PCR and recovery of the biologically active peptide. The morphology and yield of transgenic Desiree plants and tubers was unaffected. Highly stringent challenges with bacterial or fungal phytopathogens (**Phytophthora** cactorum, Fusarium solani and Erwinia carotovora) demonstrated powerful **resistance**. Tubers retained their **resistance** to infectious challenge for more than a year, and did not appear to be harmful when fed to mice. Expression of msrA1 in the cultivar Russet Burbank caused a striking lesion-mimic phenotype during leaf and tuber development, indicating its utility may be cultivar specific. Given the ubiquity of antimicrobial cationic peptides as well as their inherent capacity for recombinant and combinatorial variants, this approach may potentially be used to engineer a range of disease-**resistant** plants.

AB The present invention concerns a method of protecting plants from pathogen attack through synergistic disease **resistance** attained by applying a conventional microbicide to immunomodulated plants.

Immunomodulated plants are those in which SAR is activated and are therefore referred to as "SAR-on" plants. Immunomodulated plants may be provided in at least three different ways: by applying to plants a chem. inducer of SAR such as BTH, INA, or SA; through a selective breeding program based on constitutive expression of SAR genes and/or a disease-**resistant** phenotype; or by **transforming** plants with one or more SAR genes such as a functional form of the NIM1 gene. By concurrently applying a microbicide to an immunomodulated **plant**, disease **resistance** is unexpectedly synergistically enhanced; i.e., the level of disease **resistance** is greater than the expected additive levels of disease **resistance**.

AB **Resistance** of transgenic cultivars based on the expression of one or more **resistance** genes is sooner or later broken by pathogens whose race-producing rates are high. Thus, combining transgenesis with elicitor-induced **resistance** is a promising approach. The elicitor-induced **resistance** is based on the expression of multiple **resistance** genes, which can prevent the adaptation of pathogens to transgenic cultivars, maintain the stability of cultivars, and increase their lifespan. In this work, we used transgenic potato cultivars Temp and Superior **transformed** with Bacillus thuringiensis .DELTA.-endotoxin gene and Luk'yanovskii **transformed** with leukocyte interferon gene. Arachidonic acid (10-8 M) and sol. chitosan (5 kDa, 100 .mu.g/mL) were used as elicitors for tuber treatment. Our data showed that pretreatment with elicitors causes a 15-25% increase in both the systemic prolonged **resistance** of potato tubers to **Phytophthora** infestans and their ability to repair mech. damage.

AB Two potato cultivars (Atlantic and Shepody) were **transformed** with glucose oxidase gene from Aspergillus niger via Agrobacterium tumefaciens-mediated gene transfer. Twenty-three regenerated transgenic plants were obtained. Kanamycin **resistance**, PCR [polymerase chain reaction] amplification, nucleic acid spot hybridization, and southern blot analysis showed that the glucose oxidase gene was integrated into **transformed** potato genome. Southern blot analysis revealed the presence of 2-4 copies of glucose oxidase gene in each potato tetraploid genome. Detached transgenic potato leaves were inoculated with spores of **Phytophthora** infestans. Tests showed that the number and the size of lesions decreased, and the appearance of lesions was postponed on leaves of some transgenic lines.

AB The use of an avr gene hrmA of Pseudomonas syringae to induce systematic acquired **resistance** in **plant** cells, **plant** seeds, **plant** tissues is disclosed. Also disclosed is the use of low level expression of promoters in combination with the hrmA gene to provide broad-spectrum pathogen **resistance** against bacteria, fungi and viruses in **plant** cells, **plant** seeds, **plant** tissues and plants. Specifically, hrmA gene when expressed in tobacco plants generated **resistance** to Pseudomonas syringae, Tobacco Etch Virus (TEV), Tobacco Vein Mottling Virus (TVMV) and **Phytophthora** nicotianae.

AB Methods to identify genes, the expression of which is altered in response to pathogen infection, are provided, as well as the genes identified thereby. Arabidopsis plants of different genotypes are infected with different strains of an **oomycete**, Peronospora parasitica. RNA is isolated from each **plant**/pathogen pair and employed to prep. probes which are hybridized to a gene chip having nucleic acid sequences (probe sets) corresponding to .apprx.8200 Arabidopsis genes. Genes are then identified that are up-regulated or down-regulated in response to infection, including genes that are dependent on RPP7 or RPP8, which act via unconventional signaling cascades and are not dependent on defense regulators. Further, promoters of genes are provided that are rapidly and transiently transcribed after P. parasitica infection and are RPP7/8-dependent are significantly enriched with both novel sequence motifs and potential binding sites of known transcription factors. In addn., more than 200 genes are identified that are specifically controlled by the RPP4-dependent pathway, which mediates **resistance** of the Arabidopsis ecotype Col-0 to the Peronospora isolate Emoy2. According to their response to salicylic acid and the protein biosynthesis inhibitor cycloheximide, these genes are further subcategorized into immediate early and secondary response genes. Genes responsive to pathogen infection may be used to **transform** plants for improved **resistance** to infection.

AB Acidic osmotin-like proteins control fungal damage to plants. Genes encoding these proteins may be cloned into vectors for **transformation** of **plant**-colonizing microorganisms or plants, thereby providing a method of inhibiting fungal growth on plants. The protein was purified from chromatog. homogenates of overripe persimmon (Diospyros texana) and the gene cloned from a partial MboI library by screening with a N-terminal peptide-derived probe. The gene was expressed in Escherichia coli, yeast, and insect cell culture with a baculovirus system. The gene was introduced into potato and **transformed** tissue was shown to synthesize the protein by immunoassay and to increase **resistance** of **transformed** plants to infection with Phytopthora infestans. The protein was secreted into the extracellular fluid.

AB Elicitins are 10-kDa proteins secreted by **Phytophthora** and Pythium fungi that elicit a hypersensitive-like necrotic reaction, leading to **resistance** against fungal and bacterial **plant** pathogens. Induction of necrosis and **resistance** were previously shown to be borne by different sites of the molecule. Furthermore, sequence comparison indicated several potential residues necessary for necrosis. The role of one of these residues was previously evidenced with site-directed mutagenesis. In order to locate other necrosis-determining sites and reveal the defense-eliciting sites, we synthesized a series of synthetic peptides. Tests were performed on two types of transgenic tobacco plants, both **transformed** with a construction containing the beta-glucuronidase reporter gene, in one case controlled by the promoter of the multiple stimulus response gene str 246C and in the other by the promoter of the pathogenesis-related gene PR1a. We report that only certain peptides were found to be active. Whereas PR1a induction was consistently correlated with induction of necrosis, four peptides were observed to induce only str 246C expression without necrosis, which led to differentiate the defense-eliciting sites from the necrotic sites. From the structure-function relationships thus obtained, two different defense pathways were inferred to be independently induced by elicitins.

AB The present invention relates to a method of imparting pathogen **resistance** to plants. This involves applying a hypersensitive response elicitor polypeptide or protein in a non-infectious form to a **plant** seed under conditions where the polypeptide or protein contacts cells of the **plant** seed. The present invention is also directed to a pathogen **resistance** imparting **plant** seed. Alternatively, transgenic **plant** seeds contg. a DNA mol. encoding a hypersensitive response elicitor polypeptide or protein can be planted in soil and a **plant** can be propagated from the planted seed under conditions effective to impart pathogen **resistance** to the **plant**. Elicitor proteins and their gene sequences are provided from Erwinia chrysanthemi, E. amylovora, Pseudomonas syringae, P. solanacearum, Xanthomonas campestris cv. glycines, and X. campestris cv. pelargonii.
